ABSTRACT

A method and apparatus for allowing a user device to avoid undesired state transitions when the user is present but not performing activities is provided. The method provides for detection of activity in the proximity of the user device by monitoring for sounds via an audio input device connected to the user device. The method further provides for analysis of the detected audio signals on the audio input to determine if the sound detected matches a voice reference sample of the user of the user device. If the detected sound matches the existing voice reference sample of the user, the method provides for simulation of activities on the user device, thereby preventing the user device from performing an undesired state transition, and in turn pre-empting resource saving operations.
